

01 – DNA AND PROTEINS

1.2 - Structure and function of proteins

(part B)

1.2.4 The folding of a polypeptide to form a protein with a unique three-dimensional shape is determined by its sequence of amino acids.

Describe the factors that determine the primary, secondary, tertiary, and quaternary structure of proteins.

KEY MACROMOLECULES

Polymer
(macromolecule)

Monomer

DNA/RNA

Carbohydrate (complex sugar)

Lipid (fat)

Protein (polypeptide)

Typical amino acid

Figure 1.13: General structure of an amino acid

Primary Structure

free amino group,
N-terminus

The primary protein structure is the chain of amino acids that makes up the protein.

free carboxyl group,
C-terminus

- 1° peptide bonds between amino acids
- 2° hydrogen bonds between aa^s on nearby sections
- 3° stronger bonds between parts of chain: eg. disulphide bridge
- 4° different bondings between separate aa chains

Secondary Structure

β pleated sheet

Examples of
amino acid
subunits

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings.

Tertiary Structure

Ricin () is a [protein](#) that is [extracted](#) from the [castor bean](#) (*Ricinus communis*). Ricin may cause allergic reactions, and is toxic, though the severity depends on the route of exposure.

**Quaternary
Structure**
(two subunits)

Describe the factors that determine the primary, secondary, tertiary, and quaternary structure of proteins.

Primary

codons determine order; peptide bonds bind them

Secondary

Tertiary

Quaternary

1.2.5 Proteins are essential to cell structure and functioning.

1.2.6 Examples of proteins with specific [3D] shapes include

- enzymes,
- some hormones,
- receptor proteins,
- and antibodies.

Explain why the three-dimensional structure of a protein [its specificity] is critical to its function.

Two Key Types of Protein Molecules

I. Fibrous

usually structural (hair, connective tissue, etc); usually only show 1^o and 2^o structure; for example:

- Keratins: soft, weak, makes up hair
- Collagens: tough and strong, in cartilage, tendons, bone, etc
- Elastins: elastic proteins, allow many tissues to resume their original shape after being stretched or contracted

Two Key Types of Protein Molecules

2. Globular

*non-structural; often show 3^o and 4^o structure;
for example:*

- Enzymes: catalyse various reactions in cells
- Hormones: chemical messages between cells
- Haemoglobin: carries oxygen
- Antibodies: protect body from invading organisms

KEY = control and regulation

Haemoglobin

(quaternary
structure)

2 pairs of
polypeptide
chains

Total = 600
amino acids

Other binding
groups (Heme)

How to wreck a protein - Frying and Egg Animation

<https://www.sumanasinc.com/webcontent/animations/content/proteinstructure.html>

3D SHAPE IS CRITICAL & HIGHLY SPECIFIC to its FUNCTION.

- allows it bind to other proteins (fit together)
- allows it to receive messages from other proteins
- allows it to bind to other molecules (like DNA)
- allows it to bind to only specific molecules
(**specificity**) to help as a catalyst (speed up reactions)

hexokinase

Enzyme specificity

(no fit = no function/reduced function)

Figure 1.19: Enzyme-substrate interaction.

Peptide Hormones & Receptor Proteins

(cell communication in multicellular organisms)

Figure 1.20: Hormone secretion and binding.

Antibodies

(body self defence proteins)

Antibody = protein molecules that bind to antigens, helping body destroy invaders

Antigen = foreign molecules found on surface invading micro organisms
